Who can see what · the privacy model in plain language

For participants and organisers. Low-stakes course, mess and club feedback; not an election system. Based on SPEC.md §1–§3, §8 and §11.

1 · Seal
Your browser writes a random card and seals it in a carbon-lined envelope.

crypto: blind the message

2 · Stamp
The portal checks your institutional account and stamps the outside of the envelope. It cannot see the card.

crypto: blind signature, one per account per poll

3 · Open
Back in your browser, the stamp has come through onto the card. Nobody else has ever seen this card.

crypto: unblind and verify

4 · Use once
You hand in the card with your answers. The response service checks the stamp and keeps the card's fingerprint so it works only once.

crypto: verify signature, store nullifier

The portal (identity side) knows

✓ your institutional account, verified by Google
✓ whether your email is on this poll's list
✓ that you claimed a credential for this poll

✗ your secret card, or the stamp on it
✗ your answers
✗ whether you went on to submit

Your browser holds

- the secret card and its stamp, until you submit
- your draft answers

Nothing secret goes in links, cookies or the clipboard. After a confirmed submission it is all erased.

If this browser loses the card after you claim, it cannot be replaced for this poll.

The response service (anonymous side) knows

✓ that a validly stamped card was used for this poll
✓ your answers
✓ a one-way fingerprint of the card, so it works once

✗ your account, email or name
✗ which claim the card came from
✗ your IP address, cookies or browser details (stripped at the edge, never logged)

No database row links your account to your answers. The only value both sides share is the poll ID.

The organiser sees, only after the poll closes

✓ counts, percentages and averages for each question
✓ free-text answers, shuffled, with no names or times
✓ the total number of responses

✗ anything while the poll is open: no live counts
✗ any results if fewer than 5 people respond (permanent)
✗ a question's results if fewer than 5 people answered it
✗ who claimed, who responded, or any single response

What you still have to trust
The platform operator and its infrastructure are trusted: they could issue extra credentials or correlate network timing. Free text, small groups, unanimous answers and outside knowledge can still reveal you. A credential can be lost or shared. This is not an election system or a guarantee of absolute anonymity.
